

## Question Bank

Q.1] Explain compiler construction tools with example?

- The compiler construction can use some specialized tools that helps to implement various phases of compiler.

1) Parser Generators =>

It produces syntax analyzer from the input based on grammatical description of the programming language or CFG.

e.g.: PIC, EAM

2) Scanner Generators =>

- It produces lexical analyzer from the input consist of regular expression description based on token of a language.

- It generates finite automation to recognize the regular regular expression.

e.g.: LEX

3) Syntax directed translation engines =>

- It generates intermediate code with three address format from the input that consist of a parse tree.

- These engines have routines to traverse the parse tree & produces the intermediate code.

- In this each node of the parse tree is associated with one or more translation.

#### 4) Automatic Code Generators $\Rightarrow$

- It generates the machine language for a target machine.
- each operation of intermediate code is translated using collection of rules & taken as a I/P by code generator.

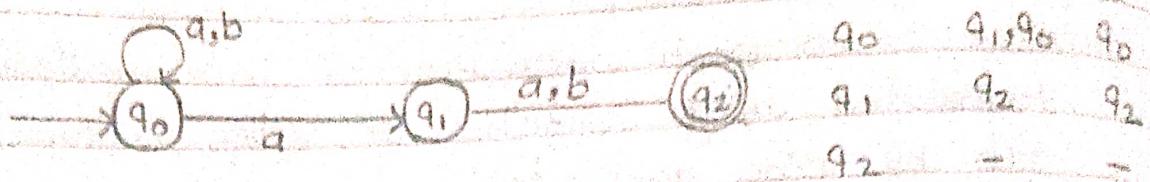

#### 5) Data flow analysis engines $\Rightarrow$

- It facilitates the gathering of information about how values are transmitted from one part of the program to other part.
- It is used in code optimization.

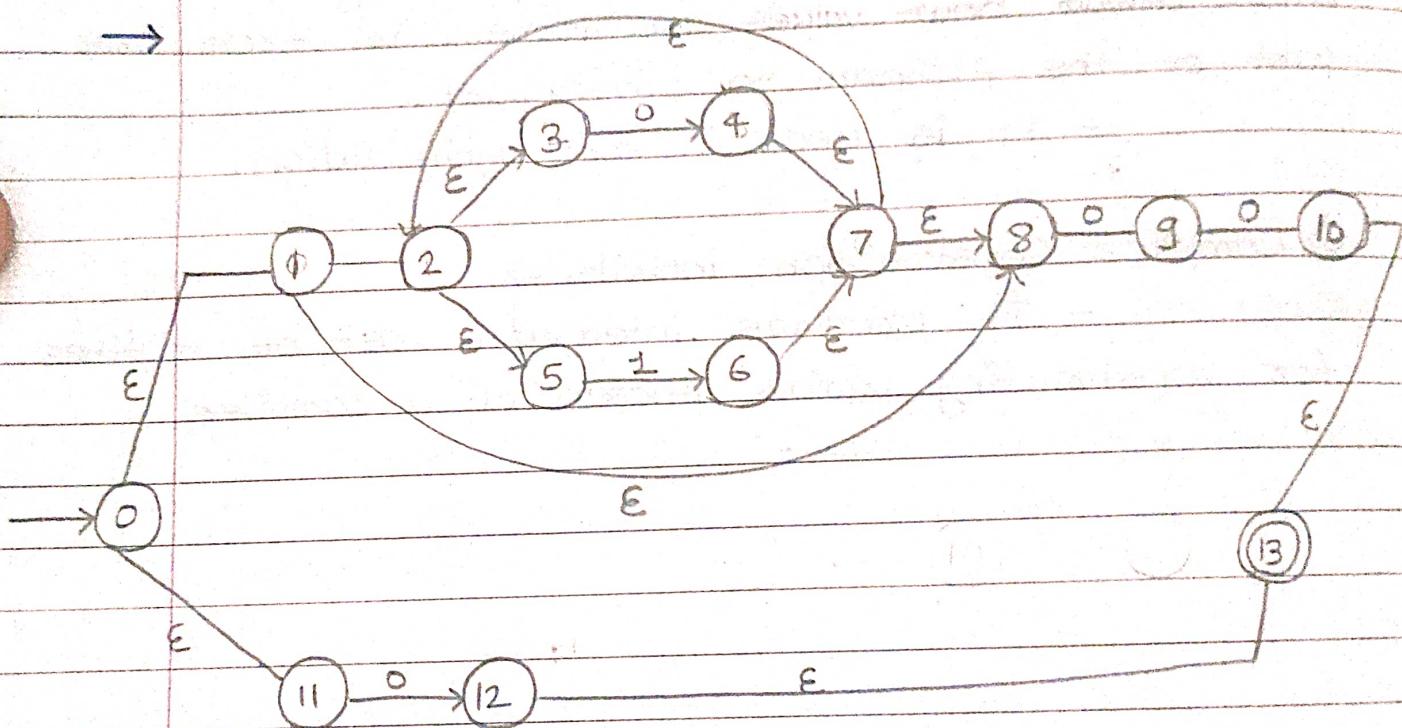

#### 6) Compiler Construction toolkits $\Rightarrow$

- It provides integrated set of routines for constructing various phases of a compiler.

Q.4] Construct Minimum State DFA for the regular expression  $(a|b)^*a(a|b)$ .

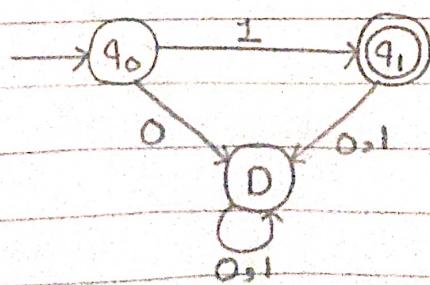

Q.5] Construct NFA for the regular expression -  
 $((0|1)^* 00) 10$

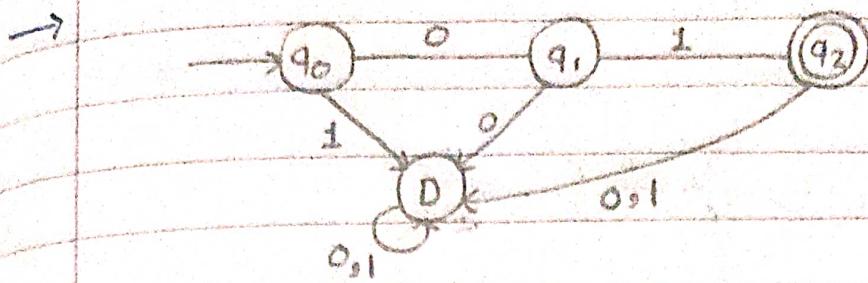

Q.6] Construct DFA for accepting the following language over an alphabet  $\{0, 1\}$

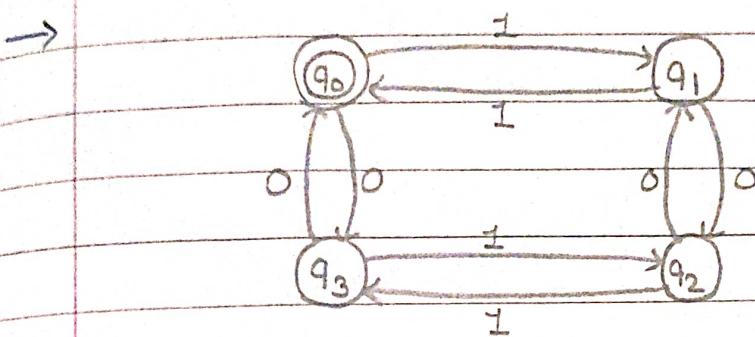

a) Accept only 1 as a String.

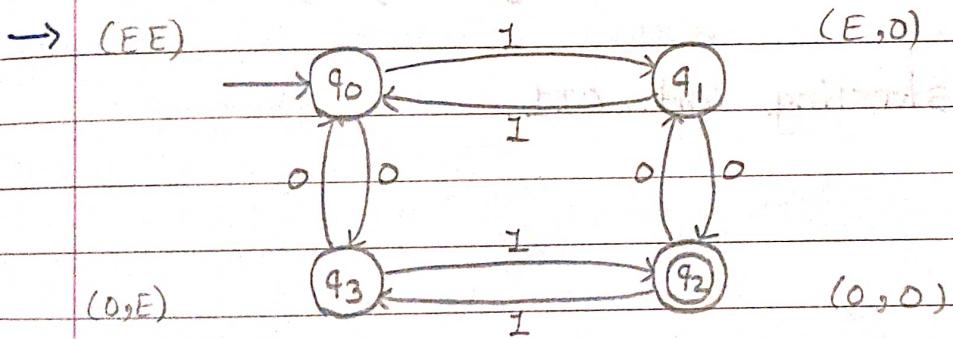

b) Accept string as 01.

c) Number of 1's is even & number of 0's is even.

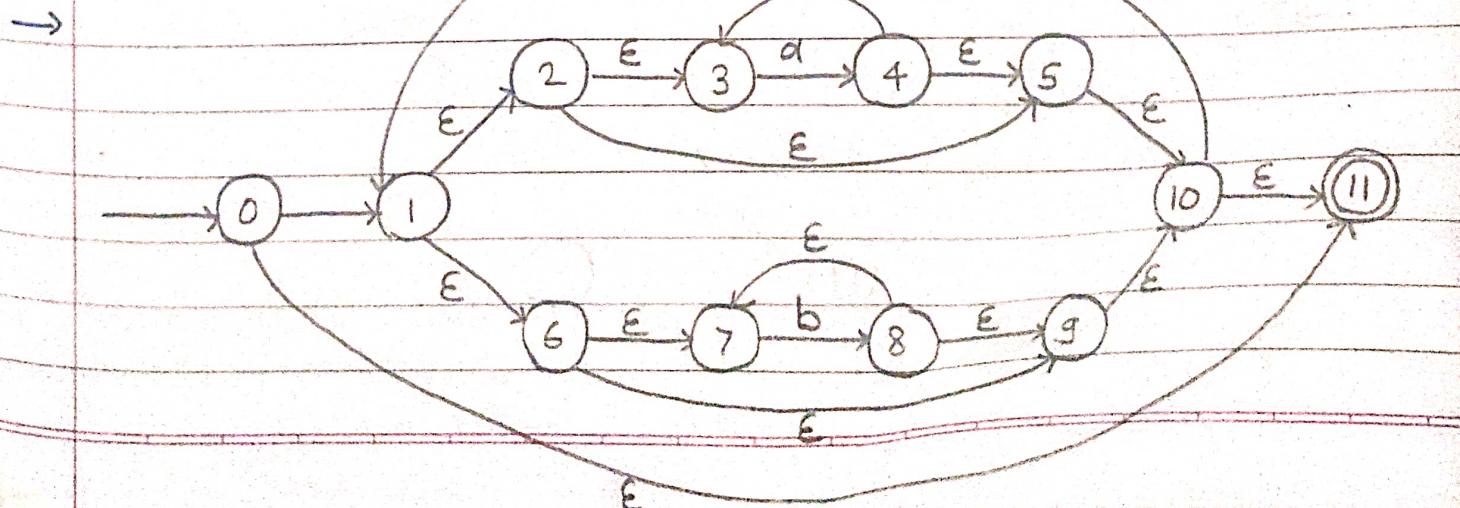

d) Number of 0-1's is odd & number of 0's is odd.

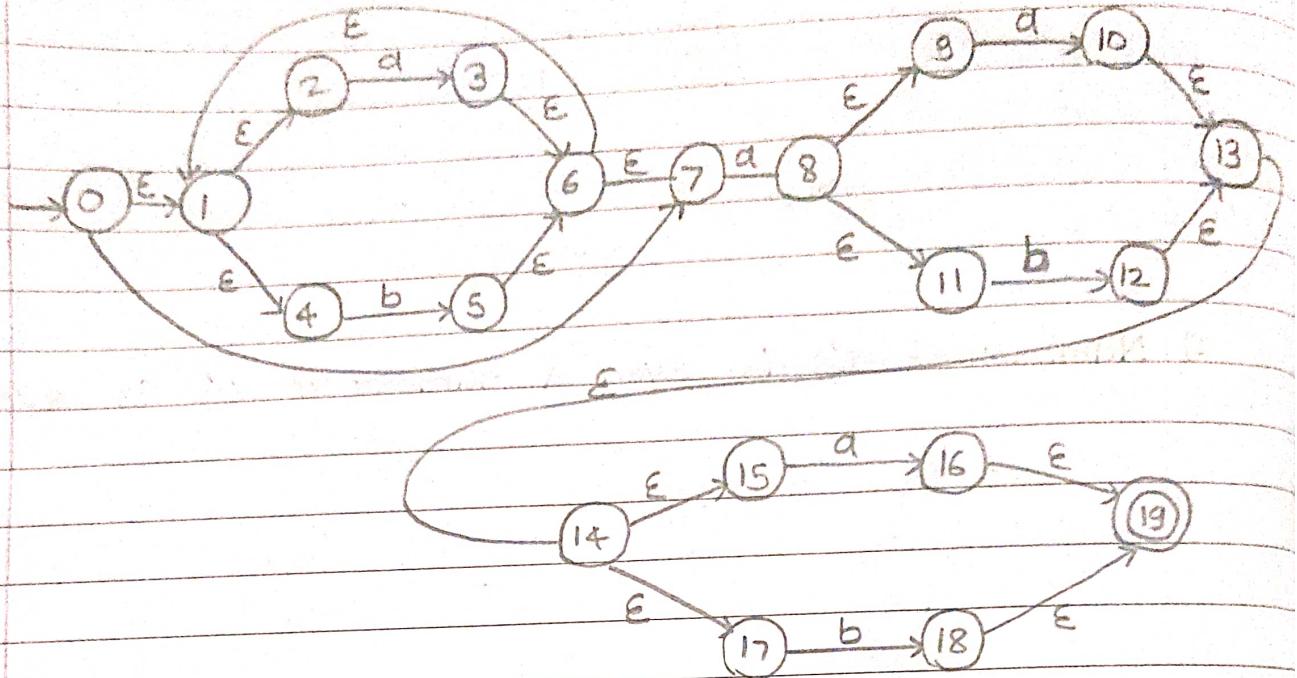

Q.7] Construct NFA using Thompsons Rule.

i)  $(a^* b^*)^*$

2)  $(a|b)^* a(a|b) (a|b)$

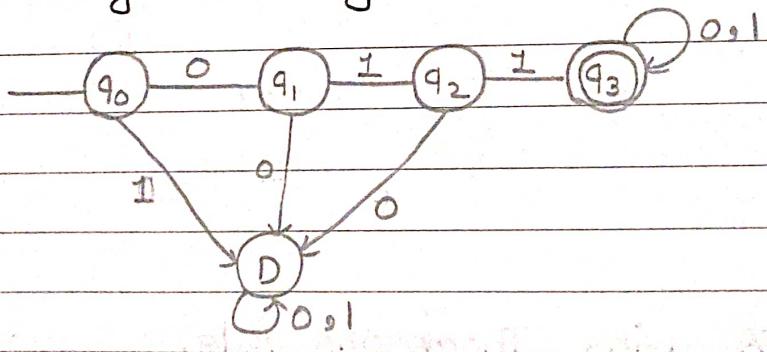

$\rightarrow$

Q.8] Construct DFA for the following language:

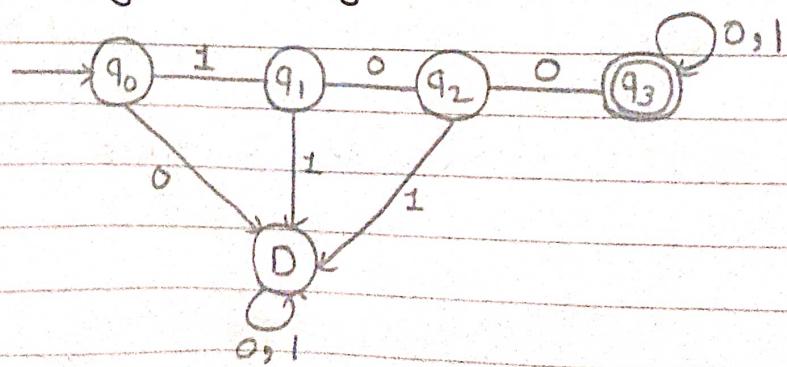

1) All strings starting with 011.

$\rightarrow$

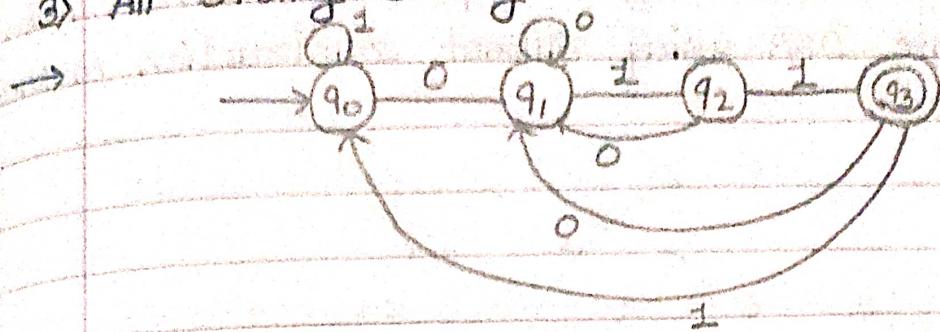

2) All strings starting with 100.

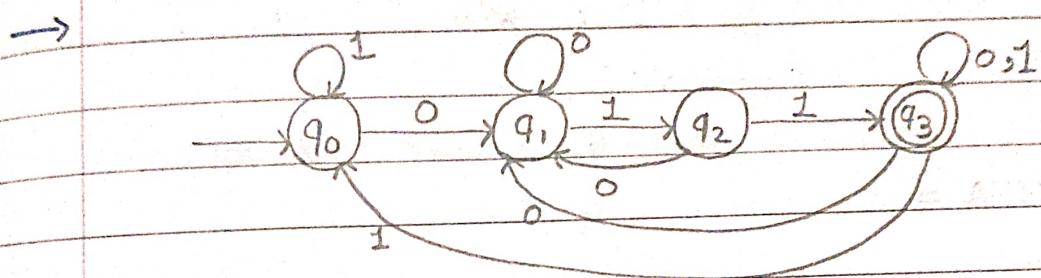

$\rightarrow$

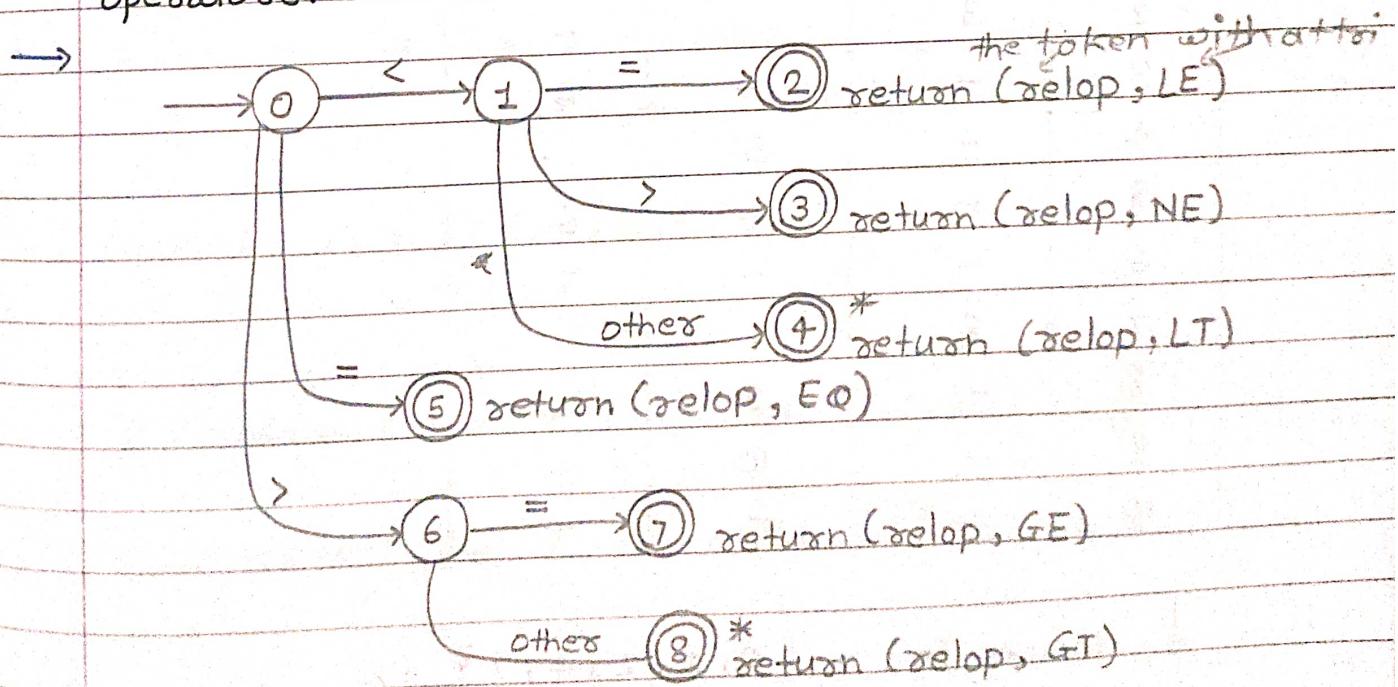

3) All string ending with 011.

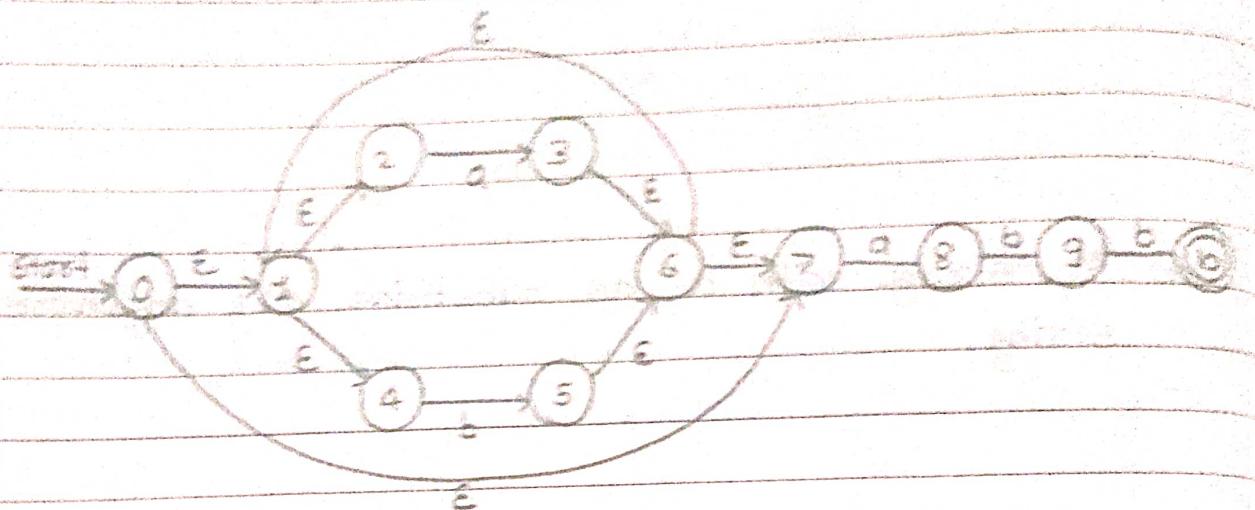

4) All string with a as substring 011 anywhere in the string.

Q.10] Draw a transition diagram to represent relational operators.

Q.11] Construct NFA from a regular expression  $(abb)^*abb$ .  
 Convert it into DFA using subset construction method.

T For NFA =

	a	b	$\epsilon$
0	-	-	1, 7
1	-	-	2, 4
2	3	-	-
3	-	-	6
4	-	5	-
5	-	-	6
6	-	-	7
7	8	-	-
8	-	9	-
9	-	10	-
10	-	-	-

$$\epsilon\text{-closure}(0) = \{0, 1, 2, 4, 7\} = \underline{\underline{A}}$$

$$\text{Move}(A, a) = \{(0, 1, 2, 4, 7), a\}$$

$$= \{3, 8\}$$

$$\begin{aligned}\text{E-closure}(A,a) &= \{ \text{E-closure}\{3,8\} \\ &= \{1,2,3,4,5,6,7,8\} = \underline{\underline{B}}\end{aligned}$$

$$\text{Move}(A,a) = \{5\}$$

$$\begin{aligned}\text{E-closure}(A,b) &= \text{E-closure}\{5\} \\ &= \{5,6,7,1,2,4\} = \underline{\underline{C}}\end{aligned}$$

$$\begin{aligned}\text{Move}(B,a) &= \{(1,2,3,4,5,6,7,8), a\} \\ &= \{3,8\} = \underline{\underline{A}}\end{aligned}$$

$$\begin{aligned}\text{E-closure}(B,a) &= \text{E-closure}\{3,8\} \\ &= \underline{\underline{B}}\end{aligned}$$

$$\begin{aligned}\text{Move}(B,b) &= \{(1,2,3,4,6,7,8), b\} \\ &= \{5,9\}\end{aligned}$$

$$\begin{aligned}\text{E-closure}(B,b) &= \text{E-closure}\{5,9\} \\ &= \{5,6,7,1,2,4,9\} = \underline{\underline{D}}\end{aligned}$$

$$\begin{aligned}\text{move}(C,a) &= \{(1,2,4,5,6,7), a\} \\ &= \{3,8\}\end{aligned}$$

$$\text{E-closure}(C,a) = \text{E-closure}(\{3,8\}) = \underline{\underline{B}}$$

$$\begin{aligned}\text{E-closure}(C,b) &= \text{E-closure}(\{1,2,4,5,6,7\}, b) \\ &= \{5\} = C\end{aligned}$$

$$\text{Move}(D,a) = B$$

$$\begin{aligned}\text{Move}(D,b) &= \{5,10\} = \{1,2,3,6,7, \underset{1}{*} 10\} = \underline{\underline{E}} \\ &\quad \text{final state}\end{aligned}$$

$\text{Move}(E, a) = \{3, 8\} = B$

$\text{Move}(E, b) = \{5\} = C$

$\therefore$  5 different sets of states we construct are:

$$1) A = \{0, 1, 2, 4, 7\}$$

$$2) B = \{1, 2, 3, 4, 6, 7, 8\}$$

$$3) C = \{1, 2, 4, 5, 6, 7\}$$

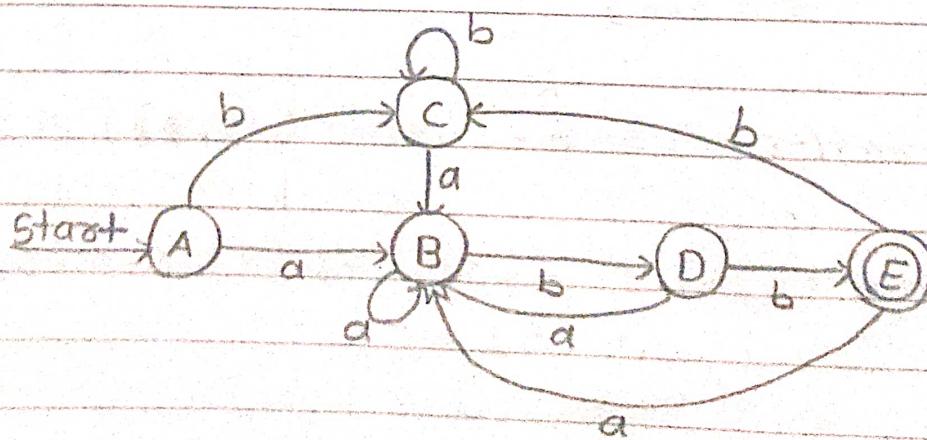

$$4) D = \{1, 2, 4, 5, 6, 7, 9\}$$

$$5) E = \{1, 2, 4, 5, 6, 7, 10\}$$

T- For DFA =

State	I/P		Symbols
	a	b	
A	B	C	
B	B	D	
C	B	C	
D	B	E	
E	B	C	

DFA =

Q.2] What is the role of lexical analysis? Explain input buffering with example?

Lexical Analysis =

- As the first phase of the compiler the main task of Lexical Analyzer is to read the input character from the source program, group them into lexemes and produce the o/p as sequence of tokens for each lexeme in the source program.

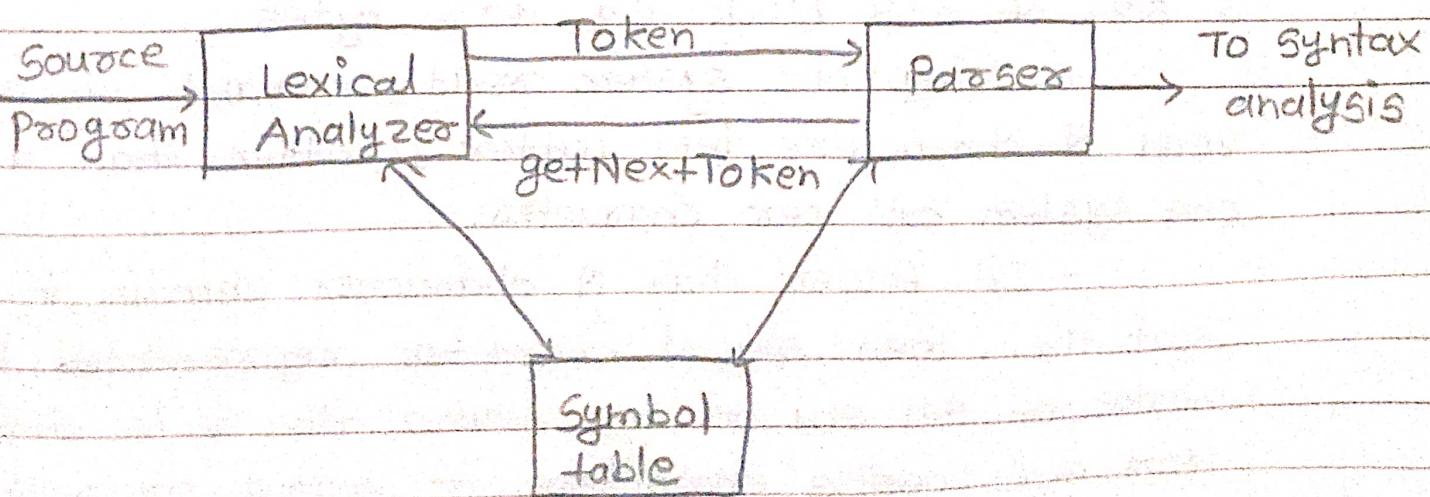

- These sequence of tokens sent to the parser for syntax analysis.

- It is common for lexical analyzer to interact with symbol table as well.

- When the Lexical analyzer identifies or discovers lexeme with identifier then it needs to be enter into symbol table.

- In some cases interaction regarding the identifiers may be read from symbol table by lexical analyzer.

- These interactions are shown in figure bellow :-

- Lexical analyzer can also perform other tasks :-

- 1) Stripping out comments & white spaces.
- 2) Correlating error messages generated by the compiler with the source program.

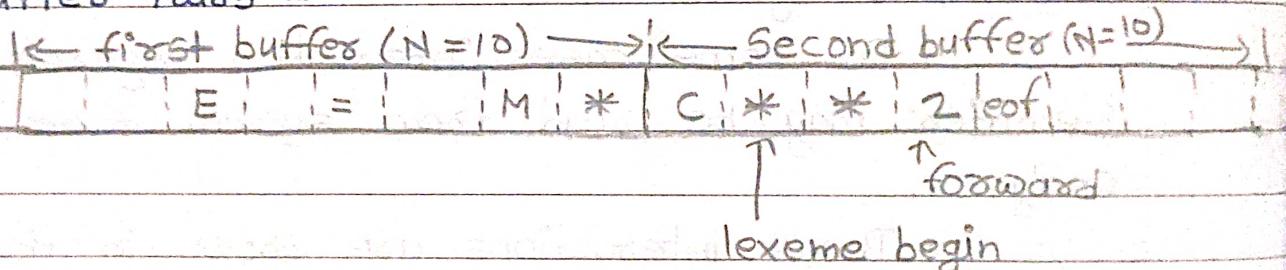

### Input Buffering =>

- Sometimes the lexical analyzer needs to look ahead some symbols to decide about the token to return.

- In C lang : we need to look after - , = , < to decide what token to return.

- So we need to introduce a two buffer scheme to handle large look-aheads safely.

### Buffer Pairs =

- Each buffer is of same size  $N$  &  $N$  is a size of disk block e.g. 4096 bytes.

- Using one system read command we can read  $N$  characters into buffer , rather than using one system call per character.

- If fewer than  $N$  character remain in the input file , then special character represented by eof, marks of the end of the source file & is different from any possible characters of source program.

- Two pointers to the I/p are mentioned :-

- 1) Pointer lexemeBegin - Marks the beginning of the current lexeme.
- 2) Pointer forward - scans ahead until a pattern match is found.

Sentinels =

- It is special character that cannot be part of source program & natural choice is the character eof.
- It is added at end of each buffers, plays the role of entire input end.

## Question Bank

Q.1] Write grammar & SDD for  $x := a+b*c+d$ . Construct annotated parse tree.

→ Grammer =

$S \rightarrow id = E$	{ gen (id.val = E.val) }
$E \rightarrow E + T$	{ E.val = E.val + T.val }
$E \rightarrow T$	{ E.val = T.val }
$T \rightarrow T * F$	{ T.val = T.val * F.val }
$T \rightarrow F$	{ T.val = F.val }
$F \rightarrow id$	{ F.val = id.name }

$$S = x = a+b*c+d$$

$$\text{id.val} = x = \text{E.val} = a+b*c+d$$

$$\text{E.val} = a+b*c + \text{T.val} = d$$

$$\text{E.val} = a + \text{T.val} = b*c$$

$$\text{T.val} = a \quad \text{T.val} = b \quad \text{F.val} = c$$

$$\text{F.val} = a \quad \text{F.val} = b \quad \text{id.val} = c$$

$$\text{id.val} = a \quad \text{id.val} = b$$

Q.2] What is S-attributed and L-attributed definition?

Implement bottom up evaluation of S-attributed for the input  $3 * 5 + 4n$ .

→

S-attributed ⇒

- S-attributed means synthesized attribute.

- An attribute is said to be synthesized attribute if its value at a parse tree node is determined from attributes values at the children of the node.

- In this semantic actions placed at right hand side. e.g.:  $A \rightarrow BC \{ \}$

- Attributes are evaluated by bottom up parser.

L-attributed ⇒

- L-attributed means inherited attribute.

- An inherited attributes is one whose value at parse tree node is determined in terms of attributes at the parent and sibling of that node.

- In this semantic actions placed anywhere.

e.g.:  $A \rightarrow BC \{ \}$ ,  $A \rightarrow \{ \} BC$ ,  $A \rightarrow A \{ \} BC$

- Attributes are evaluated by depth first traversal in bottom up parser.

Grammer =

$L \rightarrow En$

$E \rightarrow E + T$

$E \rightarrow T$

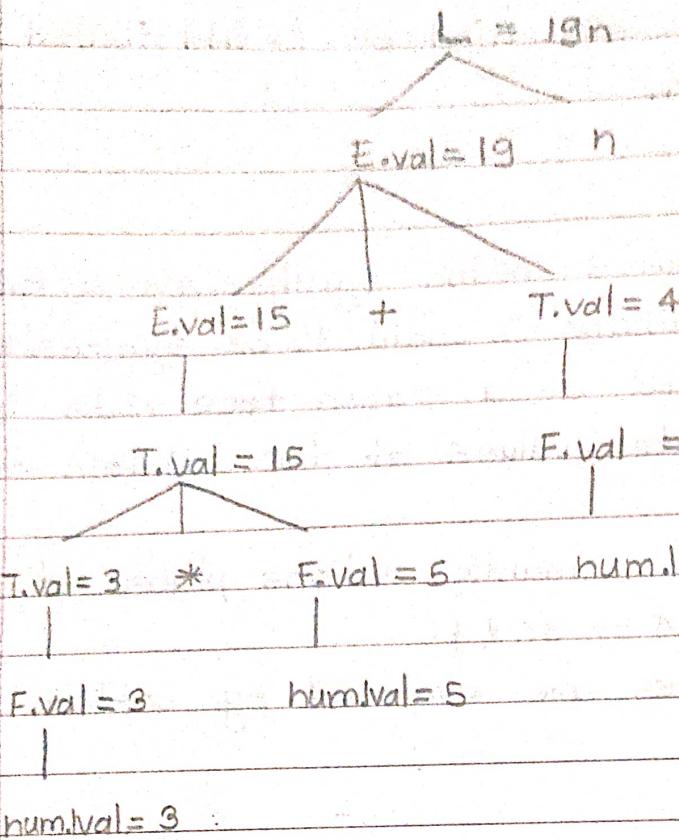

$T \rightarrow T * F$

$T \rightarrow F$

$F \rightarrow \text{Num}$

Parse Tree =

$$3 * 5 + 4n$$

Stack Implementation  $\Rightarrow$

Stack	I/P	Action
\$	$3 * 5 + 4n \$$	shift
\$ 3	$* 5 + 4n \$$	reduce $m \text{ num } F \rightarrow \text{num}$
\$ 3 *	$* 5 + 4n \$$	reduce $T \rightarrow \text{num } F$
\$ 3 *	$5 + 4n \$$	shift
\$ 3 *	$5 + 4n \$$	reduce $F \rightarrow \text{num}$
\$ 3 * 5	$+ 4n \$$	shift
\$ 3 * 5	$+ 4n \$$	reduce $T \rightarrow T * F$
\$ 15	$+ 4n \$$	reduce $E \rightarrow T$
\$ 15 +	$4n \$$	shift
\$ 15 + 4	$n \$$	reduce $F \rightarrow \text{num}$
\$ 15 + 4	$n \$$	reduce $T \rightarrow E$
\$ 19	$n \$$	reduce $E \rightarrow E + T$
\$ 19 n	\$	shift

$\therefore$  Point  $19n$

a.3] Write grammar & SDD for converting infix expression into postfix.

→

Grammar =

$$E \rightarrow E + T$$

$$E \rightarrow T$$

$$T \rightarrow T * F$$

$$T \rightarrow F$$

$$F \rightarrow \text{num}$$

SDD =

Production

$$E \rightarrow E + T$$

$$E \rightarrow T$$

$$T \rightarrow T * F$$

$$T \rightarrow F$$

$$F \rightarrow \text{num}$$

Semantic Rules

$$\{ \text{print} ("+" ); \}$$

$$\{ \}$$

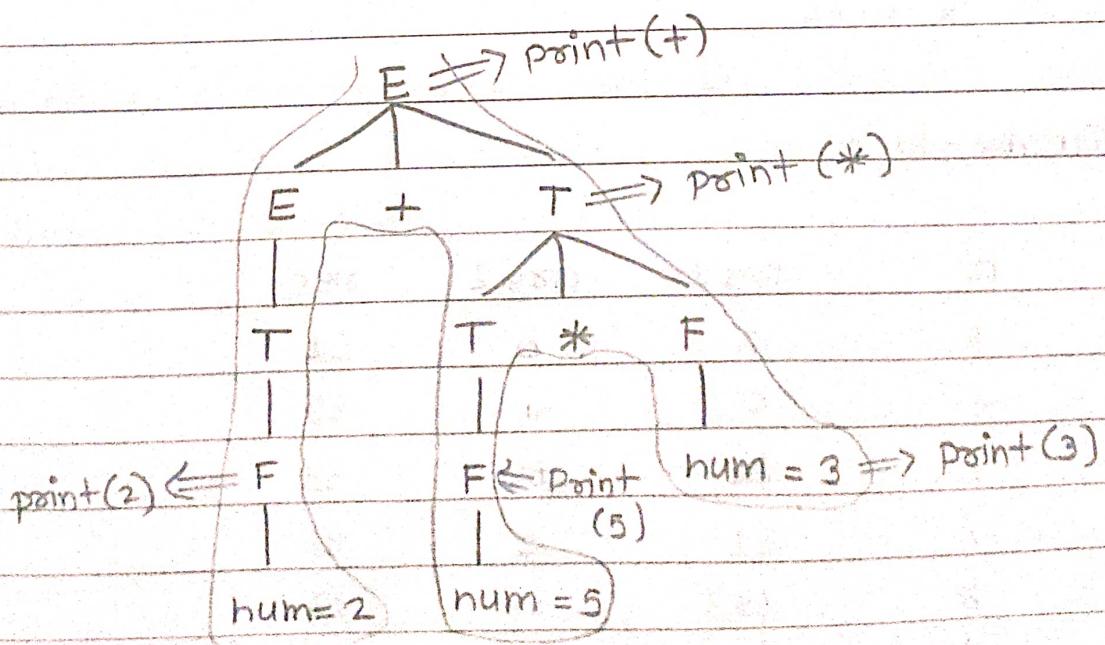

$$\{ \text{print} ("*"); \}$$

$$\{ \}$$

$$\{ \text{print} ("num.lexval"); \}$$

Example =

Infix Expression :  $2 + 5 * 3$

$\therefore$  Postfix  $\Rightarrow 253 * +$

Q.4] What is three address code? Translate the expression  $(atb) / (ctd) * (a+b/c) - d$  into quadruples, triples & indirect triples.

- Three address code is an intermediate code.
- It is used by optimizing compilers in the implementation of code-improving transformations.
- Each TAC instruction has at most three operands & it is combination of assignment and a binary operator.
- There is atmost one operator on the right side.

TAC for  $(atb) / (ctd) * (a+b/c) - d$

- 1)  $t1 = atb$
- 2)  $t2 = ctd$
- 3)  $t3 = t1 / t2$
- 4)  $t4 = t1 / c$
- 5)  $t5 = t3 * t4$
- 6)  $t6 = t5 - d$
- 7)  $x = t6$

1) Quadruple =

op	arg1	arg2	res
+	a	b	t1
+	c	d	t2
/	t1	t2	t3
/	t1	c	t4
*	t3	t4	t5
minus	t5	d	t6

2) Triple =

	OP	arg1	arg2
0	+	a	b
1	+	c	d
2	/	(0)	(1)
3	/	(0)	c
4	*	(2)	(3)
5	minus	(4)	d

3) Indirect Triple =

	OP	OP	arg1	arg2
35	(0)	+	a	b
36	(1)	+	c	d
37	(2)	/	(0)	(1)
38	(3)	/	(0)	c
39	(4)	*	(2)	(3)
40	(5)	minus	(4)	d

Q.5] Generate three address code for following boolean expression  $(a < b) \text{ or } (c < d) \text{ and } (e < f)$  using translation scheme of Boolean.

→

Q.6] What is three address code? What are the types of three address code? Write SDD to generate TAC for assignment?

- TAC is an intermediate code used by optimizing compilers in the implementation of code-improving transformations.

- Each TAC instruction has at most three operands and it is combination of assignment and a binary operator.

- There is atmost one operator on the right side.

- Following are the types of TAC :-

1) Assignment statement

2) Copy statement -  $x := y$

3) Unconditional jump -  $\text{goto } L$

4) Conditional jump - if  $x >= y \text{ goto } L$

5) Procedural call -  $\text{param } x \text{ call } p$   
 $\text{return } y$

SDD to generate TAC for assignment  $\Rightarrow$

Assignment stmt. can be in following 2 forms:

1)  $x := op \ y$

2)  $x := y \ op \ z$

Q.7] Explain back patching with suitable example.

- The codes for boolean expression insert symbolic labels for jump.
- Therefore we need separate pass to set them to appropriate addresses.
- So, we use technique called backpatching to avoid this.
- Backpatching is a process to free the unknown labels.
- In this we use 3 functions as follows :-

1) makelist(i) =

By using this fn we can create a new list.

2) Merge (P<sub>1</sub>, P<sub>2</sub>) =

Cocatenating two lists pointed by P<sub>1</sub> & P<sub>2</sub>.

3) Backpatch (P, i) =

Insert i as target label for each of the instruction on the list pointed by P.

e.g:

a < b or b < d and e < f = input expression

=>

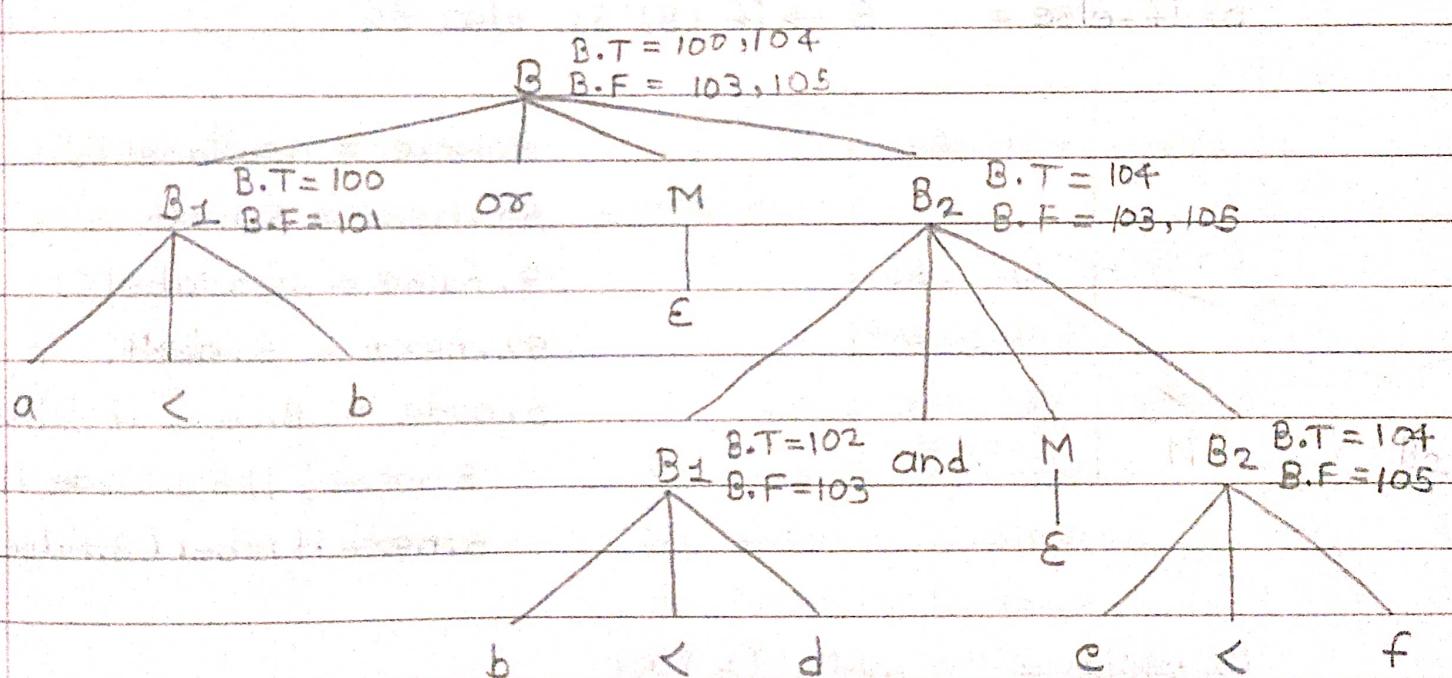

Rules required for constructing this expression =>

1) B → B<sub>1</sub> || M B<sub>2</sub> { backpatch (B<sub>1</sub>.falselist, M.instr);  
B.truealist = merge (B<sub>1</sub>.truealist +  
B<sub>2</sub>.truealist);  
B.falselist = B<sub>2</sub>.falselist; }

2)  $B \rightarrow B_1 \& M B_2$  { backpatch ( $B_1.\text{trueList}$ ,  $M.\text{insts}$ );  
 $B.\text{trueList} = B_2.\text{trueList};$   
 $B.\text{falseList} = \text{merge}(B_1.\text{falseList} +$   
 $B_2.\text{falseList});$

3)  $B \rightarrow E_1 \text{ rel } E_2$  {  $B.\text{trueList} = \text{makelist}(\text{nextinst});$   
 $B.\text{falseList} = \text{makelist}(\text{nextinst}+1);$   
 $\text{emit}(\text{'if'} E_1.\text{addr} \text{ rel. op } E_2.\text{addr})$   
 $\quad \quad \quad \text{'goto } - \text{'});$   
 $\text{emit}(\text{'goto } - \text{'});$

Annotated Parse tree =

100 : if  $a < b$  goto 106

101 : goto 102

102 : if  $b < d$  goto 104

103 : goto 107

104 : if  $c < f$  goto 106

105 : goto 107

106 : True

107 : false

Q.8] How would you generate three address code for flow of control statements.

a) if =  $S \rightarrow \text{if } (B) S_1$

	B.code	$\rightarrow B.\text{true}$	$B.\text{true} = \text{newlabel}()$
		$\rightarrow B.\text{false}$	$B.\text{false} = S_1.\text{next} = S.\text{next}$
B.true:	$S_1.\text{code}$		$S.\text{code} = B.\text{code} \parallel \text{label}(B.\text{true}) \parallel S_1.\text{code}$
B.false:	$S_1.\text{next}$		

b) if-else =  $S \rightarrow \text{if } (B) S_1 \text{ else } S_2$

	B.code	$\rightarrow B.\text{True}$	$B.\text{true} = \text{newlabel}()$
		$\rightarrow B.\text{false}$	$S_1.\text{next} = S.\text{next}$
B.true:	$S_1.\text{code}$		$B.\text{false} = \text{newlabel}()$
		goto $S.\text{next}$	$S_2.\text{next} = S.\text{next}$
B.false:	$S_2.\text{code}$		$S.\text{code} = B.\text{code} \parallel \text{label}(B.\text{true}) \parallel S_1.\text{code} \parallel \text{goto } S.\text{next} \parallel \text{label}(B.\text{false}) \parallel S_2.\text{code}$
		$S.\text{next}$	

c) while =  $S \rightarrow \text{while } (B) S_1$

	B.code	$\rightarrow B.\text{True}$	$\text{begin} = \text{newlabel}()$
		$\rightarrow B.\text{False}$	$B.\text{true} = \text{newlabel}()$
B.true:	$S_1.\text{code}$		$B.\text{false} = S_1.\text{next}()$
		goto begin	$S_1.\text{next} = \text{begin}$
B.false:	$S.\text{next}$		$S.\text{code} = \text{label}(\text{begin}) \parallel B.\text{code}$
			$\parallel \text{label}(B.\text{true}) \parallel S_1.\text{code}$
			$\parallel \text{gen}(\text{"goto"} \text{ begin})$

Example =

if ( $x < 100$  ||  $x > 200$  &&  $x \neq y$ )  $x = 0$  ;  
=>  $x = 0$  ;

TAC =

if  $x < 100$  goto L3  
goto L1  
L1 : if  $x > 200$  goto L2  
goto L4  
L2 : if  $x \neq y$  goto L3  
goto L4  
L3 :  $x = 0$   
L4 :

(b) Write the grammar & semantic rule for boolean expression (AND, OR, NOT)

→

1) AND =>

Semantic rule

$B \rightarrow B_1 \&& B_2$

$B_1.\text{true} = \text{newlabel}()$

$B_1.\text{false} = B.\text{false}$

$B_2.\text{true} = B.\text{true}$

$B_2.\text{false} = B.\text{false}$

$B.\text{code} = B_1.\text{code} \parallel \text{label}(B_1.\text{true})$   
 $\quad \quad \quad \parallel B_2.\text{code}$

2) OR =>

$B \rightarrow B_1 \parallel B_2$

$B_1.\text{true} = B.\text{true}$

$B_1.\text{false} = \text{newlabel}()$

$B_2.\text{true} = B.\text{true}$

$B_2.\text{false} = B.\text{false}$

$B.\text{code} = B_1.\text{code} \parallel \text{label}(B_1.\text{false})$   
 $\quad \quad \quad \parallel B_2.\text{code}$

3) NOT  $\Rightarrow$

Grammar

$$B \rightarrow ! B_1$$

Semantic rule

$$B_1.\text{true} = B.\text{false}$$

$$B_1.\text{false} = B.\text{true}$$

$$B.\text{code} = B_1.\text{code}$$

# Tutorial No. 6

Page No.	10	Date	10/10/2023
Page No.	10	Date	10/10/2023

Q.1] Explain following machine independent transformation techniques:

a) Common sub expression and dead code elimination =>

i) Common Sub Expression =

- The expression that has been already computed before and appears again in the code for computation is called as Common sub-expression.

- In this technique, As the name suggests, it involves eliminating the common sub expressions.

- The redundant expressions are eliminated to avoid their re-computation.

- The already computed result is used in the further program when required.

- Types of common sub-expression elimination =>

1) Local common sub-expression elimination

2) Global common sub-expression elimination.

E.g:

Before elimination:

$$a = 10;$$

$$b = a + 1 * 2;$$

$$c = a + 1 * 2;$$

$$d = c + a;$$

After elimination:

$$a = 10;$$

$$b = a + 1 * 2;$$

$$d = b + a;$$

ii) Dead Code Elimination =

- Code that is unreachable or that does not affect the program can be eliminated.

- In this technique, As the name suggests, it involves eliminating the dead code.

- The statement of the code which either never executes or are unreachable or their output is never used are eliminated.

E.g:

Before elimination:      After elimination:

```
i=0;  
if (i==1)  
{  
    a=x+5;  
}
```

b) Copy propagation and constant folding =>

i) Copy Propagation =

- Copy propagation is the process of replacing the occurrences of targets of direct assignments with their values.

- Given an assignment  $x=y$ , replace later uses of  $x$  with uses of  $y$ , provided there are no assignments to  $x$  or  $y$ .

-  $f := g$  are called copy statements.

- Use of  $g$  for  $f$ , whenever possible after copy statement.

E.g:

$x[i] = a;$        $\Rightarrow x[i] = a;$

$sum = x[i] + a;$        $sum = a + a;$

### ii) Constant Folding =

- In this technique, As the name suggests, it involves folding the constants.
- The expression that contain the operands having constant values at compile time are evaluated.
- Those expressions are then replaced with their respective results.

E.g.:

$$x := y \text{ op } z \Rightarrow x := \text{op } y$$

If  $y$  &  $z$  are constants, then the value can be computed at compilation time.

Q.2] Explain how code motion and frequency reduction used for loop optimizations?

### Code Motion =

- Code motion is used to decrease the amount of code in loop.
- It takes a statement or expression which can be moved outside the loop body without affecting the semantics of the program.

E.g.:

`while(i <= limit - 2)`

// after code motion result:

`a = limit - 2;`

`while (i <= a)`

Frequency reduction =

- It is a type in loop optimization process which is machine independent.
- In frequency reduction code inside a loop is optimized to improve the running time of program.
- It is used to decrease the amount of code in a loop.
- The objective is to reduce the evaluation frequency of expression.
- To bring loop invariant statements out of the loop.

e.g:

```
int a=2, b=3, c;  
while (i<5)  
{  
    c = pow(a,b) +  
        pow(b,a);  
    count << c;  
    i++;  
}
```

```
int a=2, b=3, c;  
c = pow(a,b) + pow(b,a);  
while (i < 5)  
{  
    count << c;  
    i++;  
}
```

Q.4 Explain different code generation issues with example.

Following issues arises during the code generation phase:

- 1) Input to code generator
- 2) Target program
- 3) Memory management
- 4) Instruction selection
- 5) Register allocation
- 6) Evaluation order

1) Input to code generator =>

- The input to the code generation consists of the intermediate representation of the source program produced by front end, together with information in the symbol table to determine run-time addresses of the data objects denoted by the names in IR.

2) Target program =>

- The output of the code generator is the target program.

- The output may be:

a) Absolute machine language =

- It can be placed in a fixed memory location and can be executed immediately.

b) Relocatable machine language =

- It allows subprograms to be compiled separately.

c) Assembly language =

- Code generation is made easier.

3) Memory management =>

- Names in the source program are mapped to addresses of data objects in run-time memory by the front end and code generator.

- It makes use of symbol table, that is, a name in a three-address statement refers to a symbol table entry for the name.

- Labels in three-address stmt have to be converted to addresses of instructions.

4) Instruction Selection =>

- The instructions of target machine should be complete and uniform.

- Instruction speeds and machine idioms are important factors when efficiency of target program is considered.
- The quality of code is determined by it's speed and size.

5) Register allocation  $\Rightarrow$

The set of variables that will reside in registers at a point in the program is selected.

6) Evaluation order  $\Rightarrow$

The order in which the computations are performed can affect the efficiency of the target code.

Q.5] Explain labeling algorithm with example?

- Labeling algorithm is used by compiler during code generation phase.

- Basically, this algorithm is used to find out how many registers will be required by a program to complete its execution.

- Labeling algorithm works in bottom up fashion.

- We will start labeling firstly child nodes & then interior nodes.

- Rules of labeling algorithm are:

1) If 'n' is a leaf node -

a) If 'n' is left child then it's value is 1.

b) If 'n' is right --- " --- is 0.

2) If 'n' is an interior node -

Lets assume L<sub>1</sub> and L<sub>2</sub> are left and right child of interior node respectively.

a) If L<sub>1</sub> == L<sub>2</sub> then value of 'n' is L<sub>1</sub>+1 or L<sub>2</sub>+1.

b) If L<sub>1</sub> != L<sub>2</sub> then value of 'n' is MAX(L<sub>1</sub>, L<sub>2</sub>)

The Labelling Algorithm =>

if n is a leaf then

if n is the leftmost child of its parent then

label(n) := 1

else

label(n) := 0

else begin

let n<sub>1</sub>, n<sub>2</sub>, ..., n<sub>k</sub> be the children of n ordered by label so that -

label(n<sub>1</sub>) >= label(n<sub>2</sub>) >= ... label(n<sub>k</sub>);

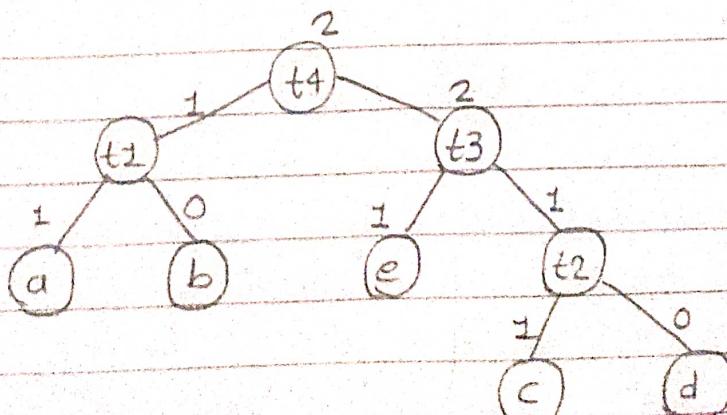

label(n) := max<sub>1 ≤ i ≤ k</sub> (label(n<sub>i</sub>) + i - 1)

end

Exp =

For binary interior nodes :

$$\text{label}(n) = \begin{cases} \max(L_1, L_2), & \text{if } L_1 \neq L_2 \\ L_1 + 1, & \text{if } L_1 = L_2 \end{cases}$$

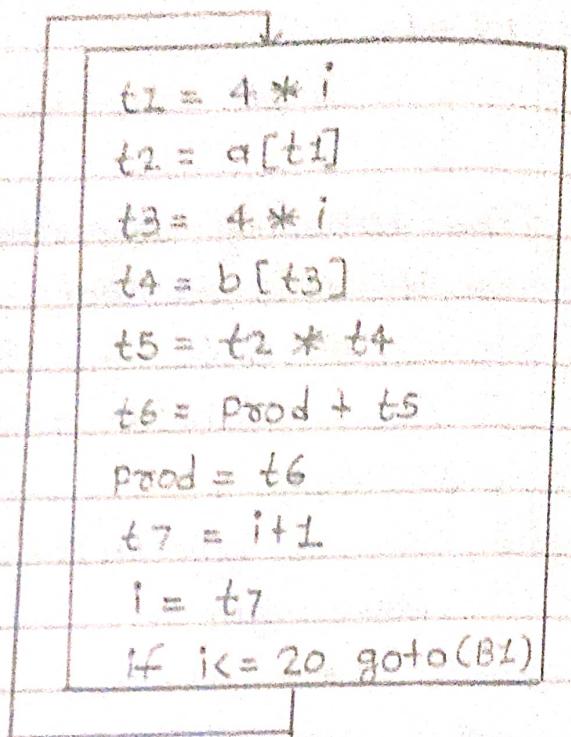

Q. 6] For the following three address statements shown below, construct flow graph & DAG :-

- 1)  $t_1 = 4 * i$
- 2)  $t_2 = a[t_1]$
- 3)  $t_3 = 4 * i$
- 4)  $t_4 = b[t_3]$
- 5)  $t_5 = t_2 * t_4$
- 6)  $t_6 = \text{prod} + t_5$
- 7)  $\text{prod} = t_6$
- 8)  $t_7 = i + 1$
- 9)  $i = t_7$
- 10) if  $i \leq 20$  goto(1)
